

The Third Collapse

Articulating the OMI Object Model

OMI is notation as cipher and cipher as notation.

Every major computing paradigm begins by collapsing a boundary

Lisp: code ↔ data
POSIX: file ↔ device
OMI: notation ↔ cipher

The structural differences between mutation and rewrite

Traditional Computing

-  - Data is mutated
-  - Control codes are non-printing characters
-  - ASCII is a lookup table
-  - Unicode is a character set
-  - Data stored at address
-  - Shift discards
-  - Reader believes projection

OMI Framework

-  - Source remains; reading changes
-  - Control codes are rewrite operators
-  - ASCII is an incidence geometry
-  - Unicode is a rewrite manifold
-  - Rewrite registered at address
-  - Rotation preserves
-  - Receipt accepts lawful interpretation

The binary source remains. The interpretation rotates.

In OMI, a cipher does not hide meaning.
A cipher declares meaning.

Control codes act as spatial notation operators

The ASCII control range (0x00..0x1F) is traditionally described as non-printing characters.

OMI restores their original force. They define spatial notation operators: they start, stop, shift, acknowledge, separate, return, and advance. They are not hidden data; they describe transitions.

The projective closure and the 15-of-16 principle

$$2^4 = 16$$

OMI reads this as
15 active states
+ 1 closure state.

The missing state
is not lost. It is the
projective center.

Like the Lisp
empty list principle,
the closure state is
both a **point** and a
space—**origin** and
container.

()

a point
and a space

Projective Center

The canonical transition law preserves all bits

$$\Delta C(x) = \text{rotl}(x,1) \text{ XOR } \text{rotl}(x,3) \text{ XOR } \text{rotr}(x,2) \text{ XOR } C$$

- **Rotations** preserve state.
- XOR contrasts differences.
- C acts as the **carried closure** of the orbit.

A shift loses information. A rotation preserves it. Nothing falls off the edge. Every rewrite leaves a witness. Every witness can carry forward.

The boundary of agreement begins with the frame

Gravity Bridge / Meta-compiler Lane

$\Omega_0 = 0! = \text{omi}---\text{imo}$

OMI is a **bounded object** doctrine for turning open-world declarations into validated, replayable, inspectable state.

The hyphen field between them is not empty space. It is the join field where a declaration becomes an inspectable object.

The OMI truth row requires a scope, a beginning, and a resolution

LL: The ket-like scope selector.

The low nibble selects.
The high nibble carries.

$\text{scope}' = \text{scope} \oplus \text{high_nibble}(\text{LL})$

NN: Antecedent candidate.

MM: Consequent resolution.

A simple pair (NN -> MM) states that "this became that," but cannot declare under what lens, scope, or context the transition occurred.
OMI opens. LL scopes. NN begins. MM resolves. IMO closes.

Topological memory and incidence grammar

An OMI object binds two sides of the same structure:

$$[\beta_0, \beta_1, \beta_2, \beta_3] \{p, q, r, s\}$$

Betti Vector $[\beta]$: Describes topology (connected components, loops, voids, higher cavities).
It asks: What topological incompleteness exists?

Schläfli Symbol $\{p, q, r, s\}$: Describes incidence.
It asks: What is the incidence grammar of the object?

The four local projective variables

The Betti variables compress into four decentralized, local projective variables inside the 128-bit frame:

- **FS** (Frame State / β_0): What frame encloses the object?
- **GS** (Group State / β_1): What group or context does it belong to?
- **RS** (Relation State / β_2): What relation is active?
- **US** (Unit State / β_3): What unit is being resolved?

The pipeline of acceptance forbids the shortcut of belief

A thing may render in a browser, appear in a DOM node, or travel through gossip. None of those **make it accepted**.

**The reader may recognize. The resolver may promote.
Only validation and receipt may *accept*.**

Safe composition through structured reflection

If truth, mirror, projection, and receipt all collapse into the same surface,
then projection becomes authority and display becomes **belief**.
OMI prevents this collapse. No single actor needs to own the whole truth.

- Actors isolate.
- Automata resolve.
- Mirrors reflect.
- Images project.
- Receipts accept.

The One-Line Canon

Lisp collapsed program and object.
POSIX collapsed storage and communication.
OMI collapses representation and interpretation:
the same binary surface is both notation and
cipher, distinguished only by the active reading,
because computation is the rewrite of interpretation,
not the mutation of data.

OMI is notation as cipher and cipher as notation.
